

India is home to 1.39 billion people, just below China but growing faster. By some projections, it will [have](#) the second largest economy in the world by 2050. In terms of climate policy, however, it doesn't get nearly as much attention as China. That's understandable in terms of India's current carbon emissions, which are now only a quarter of China's. But we need to be more forward-looking.

Currently, India's power system is heavily tilted toward coal generation, which accounts for over half of generation capacity. Twelve percent of capacity comes from hydro, and an impressive 23% from renewables (10% wind, 9% solar). Natural gas, oil, and nuclear are minor players. The national electricity plan projected that renewables will [exceed](#) coal in 2027. But given the growth of the economy, carbon emissions were projected to continue growing steadily through 2030.

In November 2021, Prime Minister Modi [announced](#) in Glasgow that India would get half its energy from renewables by 2030 as well as significantly cutting its emissions. Counting nuclear and hydro, that would mean about 60% of India's power would be zero carbon. Modi set a target of 2070 for net zero. Given that rapid growth of India's economy, this would mean a huge effort to install renewables and other zero-carbon power sources. Prior to Glasgow, the NRDC had [concluded](#) that India was on track to meet its previous commitment to have 40% non-fossil fuel power generation by 2030.

For many years, India's position was that the developed world was responsible for cutting emissions while economic growth should be the priority for developing countries. It was only in 2010 that India [agreed](#) that all countries should take responsibility for controlling their own emissions, but there was backsliding the following year at the next round of international negotiations. India then became more firmly committed to climate policy. Much of the shift may have been due to recognition that renewables would provide more energy independence and would help get India's crippling urban air pollution under control. India's desire to carry more weight on the global stage may also have been a motivation. It's also relevant that India is extremely vulnerable to climate change due to its reliance on monsoons.

As in the U.S., the national government isn't the only presence in terms of climate policy. Mumbai, with a population of 21 million, now has a [roadmap](#) for reaching net-zero emissions by 2050. The roadmap calls for Mumbai to get half its electricity from renewables by 2030 and 90% by 2050. Mumbai is on a peninsula and faces severe risks from sea level rise.

India's willingness to commit to a net zero target is an important change, with hopeful implications globally. Meeting its target will not be easy. The 2070 target, however, though

admirable, is probably [not](#) going to be enough to meet the goal of keeping global warming near 1.5 °C. Hopefully, Mumbai will serve as a model for more state and local climate action. Like the rest of the world, India is going to have to up its game. But at least it's heading briskly in the right direction.
